

SRP_Regex Error

Returns the last error that occurred when using SRP_Regex.

```
Error = SRP_Regex("Error")
```

Returns

An error message if there was an error on the last SRP_Regex call, "" if not.

Remarks

The Error service returns an error message describing the error that occurred the last time an SRP_Regex service was called. This means that when the Match service, for example, returns 0, it might be due to an error in the pattern that was given to it rather than it failing the pass. The example below shows how to test for that error.

Examples

```
Pattern = '*@mydomain\.com$'
Result = SRP_Regex('Match', 'john.doe@mydomain.com', Pattern)
If Results EQ 0 then
    Error = SRP_Regex('Error')
    If Error NE "" then
        // there was an error doing the match: "regex_error(error_badrepeat): One of *?+{ was not
preceded by a valid regular expression."
    end
end
end
```
